## Fast Ways to Traverse an Array: Use a Limit Pointer

```
int x[] = {0xd4c3b2a1, 0xd4c3b200, 0x12345684};
int cnt = (int)(sizeof(x) / sizeof(*x));
```

```
int *ptr;
int *xptr;
ptr = x;
xptr = ptr + cnt;
```

xptr is a **loop limit pointer**  
it points **1 element past**  
the end of the array

```
while (ptr < xptr) {
    printf("%#x\n", *ptr);
    ptr++;
}
```

//or &x[0]

cnt = 3;  
actual space used =  
cnt \* sizeof(\*x);  
= 12

```
% ./a.out
0xd4c3b2a1
0xd4c3b200
0x12345684
```

## C Precedence and Pointers

- ++ -- pre and post increment combined with pointers can create code that is complex, hard to read and difficult to maintain
- Use () to help readability

Operator	Description	Associativity
() [] . -> ++ --	Parentheses or function call Brackets or array subscript Dot or Member selection operator Arrow operator Postfix increment/decrement	left to right
++ -- + - ! ~ (type) * & sizeof	Prefix increment/decrement Unary plus and minus not operator and bitwise complement type cast Indirection or dereference operator Address of operator Determine size in bytes	right to left
* / %	Multiplication, division and modulus	left to right
+ -	Addition and subtraction	left to right
<< >>	Bitwise left shift and right shift	left to right
< <= > >=	relational less than/less than equal to relational greater than/greater than or equal to	left to right
== !=	Relational equal to or not equal to	left to right
&&	Bitwise AND	left to right
^	Bitwise exclusive OR	left to right
	Bitwise inclusive OR	left to right
&&	Logical AND	left to right
	Logical OR	left to right
? :	Ternary operator	right to left
= += -= *= /= %= &= ^=  = <<= >>=	Assignment operator Addition/subtraction assignment Multiplication/division assignment Modulus and bitwise assignment Bitwise exclusive/inclusive OR assignment	right to left
,	comma operator	left to right

common	With Parentheses	Meaning
*p++	*(p++)	(1)The Rvalue is the object that p points at (2)increment pointer p to next element ++ is higher than *
(*p)++		(1)Rvalue is the object that p points at (2)increment the object
*++p	*(++p)	(1)Increment pointer p first to the next element (2)Rvalue is the object that the incremented pointer points at
++*p	++(*p)	Rvalue is the incremented value of the object that p points at

## Example of a hard-to-understand pointer statement

```
int array[] = {2, 5, 7, 9, 11, 13};  
int *ptr = array;  
int x;
```

```
x = 1 + (*ptr++)++; // yuck!!
```

common	Alternate	Meaning
*p++	*(p++)	The Rvalue is the object that p points at; then increment pointer p to next element
(*p)++		The Rvalue is the object that p points at; then increment the object
++p	*(++p)	Increment pointer p first to the next element; the Rvalue is the object that the incremented pointer points at
++*p	++(*p)	The Rvalue is the incremented value of the object that p points at

```
/* Same as the one line above */  
x = 1 + *ptr;           // x = 1 + *ptr (2) = 3;  
  
*ptr = *ptr + 1;        // (*ptr)++ is array[0]= 2 + 1;  
  
ptr = 1 + ptr;          // ptr = &array[1] = now points at 5
```

# C Strings - 1

- C does not have a **dedicated type** for strings
- Strings are an **array of characters** terminated by a **sentinel termination character**
- `'\0'` is the **Null termination character**; has the **value of zero** (do not confuse with `'0'`)
- An **array of chars** contains **a string only when** it is terminated by a `'\0'`
- **Length of a string** is the **number of characters** in it, not including the `'\0'`
- Strings in C are **not** objects
  - **No embedded information about them**, you **just have a name** and a memory **location**
  - You **cannot use + or +=** to concatenate strings in C
  - For example, you must **calculate string length** using code at runtime looking for the sentinel

## C Strings - 2

- First '`\0`' encountered from the start of the string always indicates the end of a string
- The '`\0`' **does not have to be** in the **last element in the space allocated to the array**
  - But String length is always **less than the size of the array** it is contained in
- In the example below, the array `buf` contains two strings (but only `cat` is seen as the string)
  - One string starts at `&(buf[0])` is `"cat"` with a string length of 3
  - The other string starts at `&(b[4])` is `"o"` with a string length of 1
  - `"o"` has two bytes: `'o'` and `\0`

string length: number of char (= 3)

string length: number of char (= 1)

index	0	1	2	3	4	5
buf	'c'	'a'	't'	'\0'	'o'	'\0'
	0x63	0x61	0x74	0x00	0x6f	0x00

length (size) of the array in number of char (= 6)

## Defining Strings: Initialization

- When you combine the automatic length definition for arrays with double quote("") **initialization**
  - Compiler automatically adds the null terminator '\0' for you

```
char a[4] = {'c', 'a', 't', '\0'};
char b[] = "cat";
char c[] = {'c', 'a', 't', '\0', 'a', 'b'};
char empty[] = "";
```

*// compiler calculates size, adds '\0'*  
*// array size 6, first string length 3*  
*// empty string - contains '\0'*  
*// string length = 0*

## Background: Different Ways to Pass Parameters

- **Call-by-reference (or pass by reference)**

- Parameter in the called function is an **alias** (references the same memory location) for the supplied argument
- Modifying the parameter modifies the calling argument

### **Call-by-value** (or pass by value) (C)

- What **Called** Function Does
  - Passed Parameters are used like local variables
  - **Modifying** the **passed parameter** in the **function** is **allowed** just like a **local variable**
  - So, writing to the parameter, **only** **changes** the **copy**
- The **return value** from a function in C is **by value**

## Passing Parameters – Call by Value Example

```
int main(void)
{
    int x = 5;
    inc(x); // makes a copy of x
    printf("%d\n", x); // 5 or 6 ?
}

void inc(int i) // i is local to inc
{
    ++i;
}
```

if this was an expression like `inc(x+1)` it evaluates and stores the result in the memory allocated for the copy

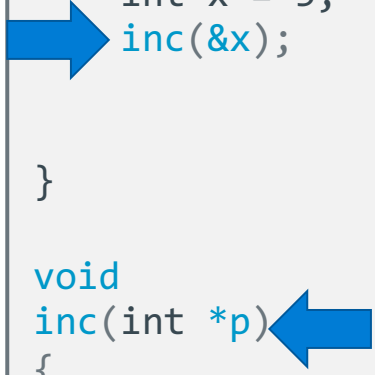

- when `inc(x)` is called, a copy of `x` is made to another memory location
  - `inc()` cannot change the variable `x` since `inc()` does not have the address of `x`, it is local to `main()` so, 5 is printed
- The `inc()` function is free to change its copy of the argument (just like any local variable) remember it does NOT change the parameter in `main()`

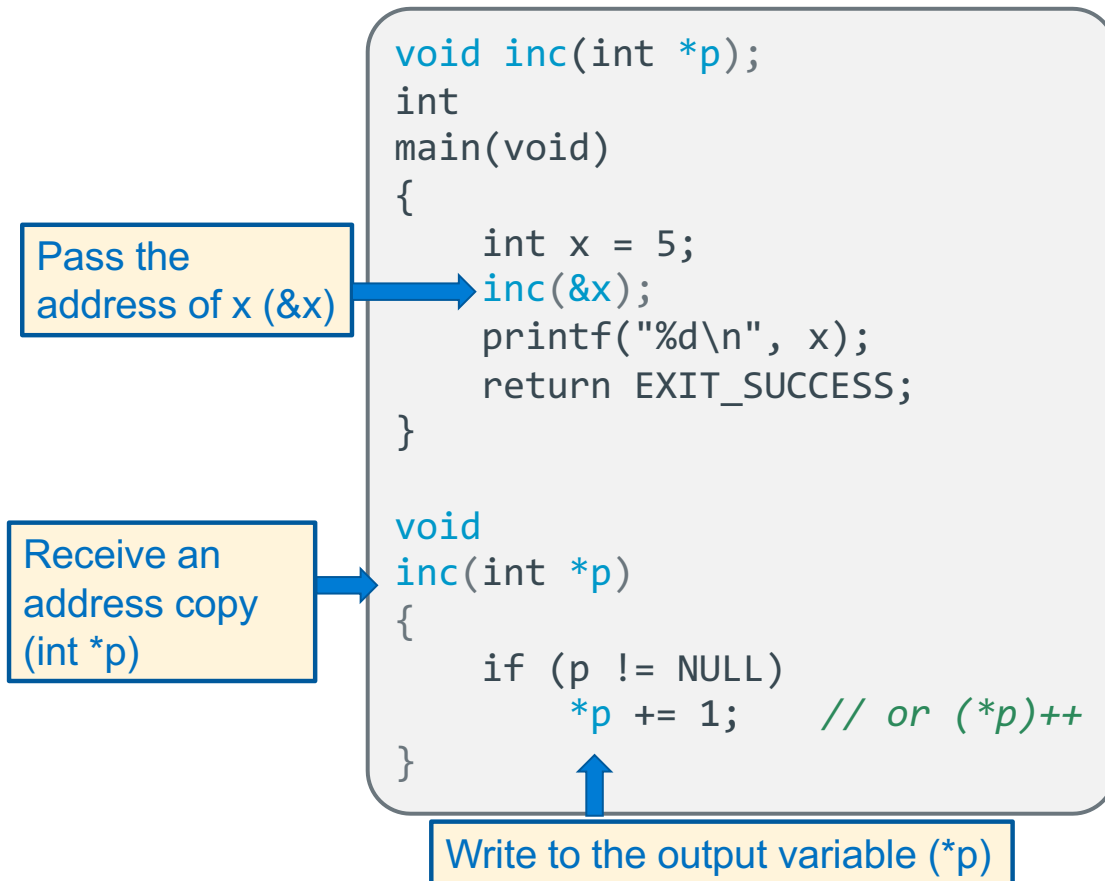

## Output Parameters (Mimics Call by Reference)

- Passing a pointer parameter with the intent that the called function will use the address it to store values for use by the calling function, then pointer parameter is called an **output parameter**
- To pass the address of a variable x use the **address operator** (&x) or the contents of a pointer variable that points at x, or the name of an array (the arrays address)
- To be receive an address in the called function, define the corresponding parameter type to be a pointer (add \*)
  - It is common to describe this method as: "pass a pointer to x"
- C is still using "pass by value"
  - we pass the **value** of the address/pointer in a **parameter copy**
  - **The called routine** uses the address to change a variable in the caller's scope

```
void inc(int *p);  
int  
main(void)  
{  
    int x = 5;  
    inc(&x);  
}  
  
void  
inc(int *p)  
{  
  
}  
}
```

## Example Using Output Parameters

### At the Call to inc() in main()

1. Allocate space for p
2. Copy x's address into p

### With a pointer to X,

inc() can change x in main()  
this is called a side effect

p just like any other local variable

# Array Parameters: Call-By-Value or Call-By-Reference?

- **Type []** array parameter is automatically “**promoted**” to a pointer of type **Type \***, and a copy of the *pointer* is *passed by value*

the name is the address, so this is passing a pointer to the start of the array

```
void passa(int []);
int main(void)
{
    int numbers[] = {9, 8, 1, 9, 5};

    passa(numbers);
    printf("numbers size:%lu\n", sizeof(numbers)); // 20
    return EXIT_SUCCESS;
}
```

```
void passa(int a[])
{
    printf("a size:%lu\n", sizeof(a)); // 4
    return;
}
```

## IMPORTANT:

See the size difference 20 in main() in passa() is 4 bytes (size of a pointer) on pi-cluster and 8 on ieng6

- Call-by-value pointer (callee can change the pointer parameter to point to something else!)
- Acts like call-by-reference (called function can change the contents caller's array)

## Arrays As Parameters: What is the size of the array?

- It's tricky to use arrays as parameters, as **they are passed as pointers to the start of the array**
  - In C, Arrays do not know their own size and at runtime there is no “bounds” checking on indexes

“inside” the body of sumAll(), the question is:  
how big is that array? all I have is a POINTER to the first element.....

so sizeof(a) is the size of a pointer, not the array it points at

Net result: sz is a 1 on picluster

```
int sumAll(int *);

int main(void)
{
    int numb[] = {9, 8, 1, 9, 5};
    int sum = sumAll(numb);

    return EXIT_SUCCESS;
}

int sumAll(int *a)
{
    int i, sum = 0;
    int sz = (int) (sizeof(a)/sizeof(*a));
    for (i = 0; i < sz; i++) // this does not work
        sum += a[i];
}
```

# Arrays As Parameters, Approach 1: Pass the size

## Two ways to pass array size

1. pass the **count** as an additional argument
2. add a **sentinel element** as the last element

remember you can only use `sizeof()` to calculate element count where the array is defined

```
int sumAll(int *a, int size);
int main(void)
{
    int numb[] = {9, 8, 1, 9, 5};
    int cnt = sizeof(numb)/sizeof(numb[0]);

    printf("sum is: %d\n", sumAll(numb, cnt));
    return EXIT_SUCCESS;
}
```

```
int sumAll(int *a, int size)
{
    int sum = 0;
    int *end;
    end = a + size;

    while (a < end)
        sum += *a++;
    return sum;
}
```

same as:  
sum = sum + \*a;  
a++;

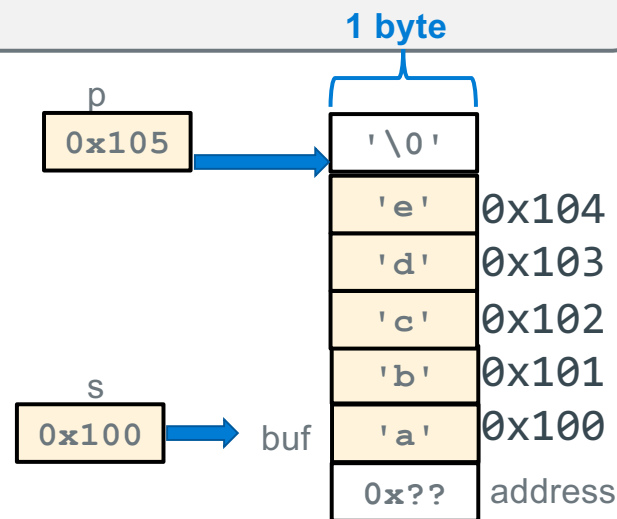

## Arrays As Parameters, Approach 2: Use a sentinel element

- A **sentinel** is an element that contains a value that is not part of the normal data range
  - Forms of 0 are often used (like with strings). Examples: '\0', NULL

```
int strlen(char *a); // returns number of chars in string, not counting \0
int main(void)
{
    char buf[] = {'a', 'b', 'c', 'd', 'e', '\0'}; // or buf[] = "abcde";

    printf("Number of chars is: %d\n", strlen(buf));
    return EXIT_SUCCESS;
}
```

```
/* Assumes parameter is a terminated string */
int strlen(char *s)
{
    char *p = s;
    if (p == NULL)
        return 0;
    while (*p++)
        ;
    return (p - s - 1);
}
```

## Reference: Some String Routines in libc (#include <string.h>)

Function	Description
<code>strlen(<i>str</i>)</code>	returns the # of chars in a C string (before null-terminating character).
<code>strcmp(<i>str1</i>, <i>str2</i>)</code> , <code>strncmp(<i>str1</i>, <i>str2</i>, <i>n</i>)</code>	compares two strings; returns 0 if identical, <0 if <b><i>str1</i></b> comes before <b><i>str2</i></b> in alphabet, >0 if <b><i>str1</i></b> comes after <b><i>str2</i></b> in alphabet. <b><i>strncmp</i></b> stops comparing after at most <b><i>n</i></b> characters.
<code>strchr(<i>str</i>, <i>ch</i>)</code> <code>strrchr(<i>str</i>, <i>ch</i>)</code>	character search: returns a pointer to the first occurrence of <b><i>ch</i></b> in <b><i>str</i></b> , or <b>NULL</b> if <b><i>ch</i></b> was not found in <b><i>str</i></b> . <code>strrchr</code> find the last occurrence.
<code>strstr(<i>haystack</i>, <i>needle</i>)</code>	string search: returns a pointer to the start of the first occurrence of <b><i>needle</i></b> in <b><i>haystack</i></b> , or <b>NULL</b> if <b><i>needle</i></b> was not found in <b><i>haystack</i></b> .
<code>strcpy(<i>dst</i>, <i>src</i>)</code> , <code>strncpy(<i>dst</i>, <i>src</i>, <i>n</i>)</code>	copies characters in <b><i>src</i></b> to <b><i>dst</i></b> , including null-terminating character. Assumes enough space in <b><i>dst</i></b> . Strings must not overlap. <b><i>strncpy</i></b> stops after at most <b><i>n</i></b> chars, and <u>does not</u> add null-terminating char.
<code>strcat(<i>dst</i>, <i>src</i>)</code> , <code>strncat(<i>dst</i>, <i>src</i>, <i>n</i>)</code>	concatenate <b><i>src</i></b> onto the end of <b><i>dst</i></b> . <b><i>strncat</i></b> stops concatenating after at most <b><i>n</i></b> characters. <u>Always</u> adds a null-terminating character.
<code>strspn(<i>str</i>, <i>accept</i>)</code> , <code>strcspn(<i>str</i>, <i>reject</i>)</code>	<b><i>strspn</i></b> returns the length of the initial part of <b><i>str</i></b> which contains <u>only</u> characters in <b><i>accept</i></b> . <b><i>strcspn</i></b> returns the length of the initial part of <b><i>str</i></b> which does <u>not</u> contain any characters in <b><i>reject</i></b> .

## Do not overuse strlen()

- C string library function `strlen()` calculates string length **at runtime**
- **Do not overuse `strlen()`, as it walks the array each time called**

```
int count_e(char *s) //  $O(n^2)$  !!!  
{  
    int count = 0;  
    if (s == NULL)  
        return 0;  
    for (int j = 0; j < strlen(s); j++) {  
        if (s[j] == 'e')  
            count++;  
    }  
    return count;  
}
```

```
int count_e(char *s) //  $O(n)$  !!!  
{  
    int count = 0;  
    if (s == NULL)  
        return 0;  
    while (*s) {  
        if (*s++ == 'e')  
            count++;  
    }  
    return count;  
}
```

## The NULL Constant and Pointers

- **NULL is a constant** that **evaluates to zero (0)**
- You **assign a pointer variable to contain NULL** to **indicate that the pointer does not point at anything**
- A **pointer variable** with a **value of NULL** is called a “**NULL pointer**” (invalid address!)
- Memory location 0 (address is 0) is not a valid memory address in any C program
- Dereferencing NULL at runtime will cause a program fault (segmentation fault)!

```
p = NULL;  
i = *p;           /* segmentation fault! */  
*(int *)900000 = 25; /* cast 900000 to a pointer */  
                  /* if writeable address space, it works */  
                  /* that memory location just changed */
```

## Using the NULL Pointer

- Many functions return NULL to indicate an error has occurred

```
/* these are all equivalent */  
int *p = NULL;  
int *p = (int *)0;    // cast 0 to a pointer type  
int *p = (void *)0;   // automatically gets converted to the correct type
```

- NULL is considered “false” when used in a Boolean context
  - **Remember: false expressions** in C are defined to be zero or NULL
- The following two are equivalent (the second one is preferred for readability):

```
if (p) ...  
if (p != NULL) ...
```

## Simple String IO - Reading

Task	Example Function Calls
Read a string	<pre>#include &lt;stdio.h&gt;  char *strptr; char myStr[BFSZ];  strptr = fgets(myStr, BFSZ, stdin);</pre> <div>must pass the size of the array so fgets() knows how much space there is</div>

`char *fgets(char array[ ], int size, FILE *stream)`

- `char *` is a pointer (address) to an array of char
- reads in at most **one less than size** characters from **stream** and stores them into **array**
- Reading stops after an **EOF** or a newline '\n'
  - If a newline ('\n') is read, it is stored into the buffer
  - **A terminating null byte ('\0') is always stored after the last character in the buffer**

t	h	i	s		i	s		a	s	t	r	i	n	g	\n	\0
---	---	---	---	--	---	---	--	---	---	---	---	---	---	---	----	----

- Returns a **NULL at end of file** (or a read failure), otherwise a pointer to array (pointers later...)
- See `man 3 fgets`

## Pointer returns from a function call

```
char *next(char *ptr)
{
    if (ptr == NULL)
        return NULL;

    while ((*ptr != '\0') && (*ptr != ','))
        ptr++;

    if (*ptr == ',')
        return ++ptr;
    return NULL;
}
```

```
#include <stdlib.h>
#include <stdio.h>
#define BUFSZ 512
char *next(char *);

int main()
{
    char buf[BUFSZ];
    char *ptr;

    while (fgets(buf, BUFSZ, stdin) != NULL) {
        printf("buf: %s\n", buf);

        if ((ptr = next(buf)) != NULL)
            printf("after: %s\n", ptr);
        else
            printf("no comma found\n");
    }
    return EXIT_SUCCESS;
}
```

## Returning a Pointer To a Local Variable (Dangling Pointer)

- There are many situations where a function will return a pointer, but a function must never return a pointer to a memory location that is **no longer valid** such as:
  - Address of a **passed parameter copy** as the caller may or will deallocate it after the call
  - Address of a **local variable (automatic)** that is invalid on function return
- These errors are called a **dangling pointer**

n is a parameter with the scope of bad\_idea it is no longer valid after the function returns

```
int *bad_idea(int n)
{
    return &n; // NEVER do this
}
```

a is an automatic (local) with a scope and **lifetime** within bad\_idea2 a is no longer a valid location after the function returns

```
int *bad_idea2(int n)
{
    int a = n * n;
    return &a; // NEVER do this
}
```

```
/*
 * this is ok to do
 * it is NOT a dangling
 * pointer
 */

int *ok(int n)
{
    static int a = n * n;
    return &a; // ok
}
```

## Copying Strings: Use the Sentinel; libc: strncpy()

index	0	1	2	3	4	5
char	'H'	'e'	'l'	'l'	'o'	'\0'

```
// strncpy adds a length limit on copy
char str1[6];
int cnt = (int)(sizeof(str1) / sizeof(str1[0]));

strncpy(str1, "hello", cnt); // \0 copied
strncpy(str1, "hello", cnt - 1); // \0 not copied
```

```
char *strncpy(char *s0, char *s1, int len)
{
    char *str = s0;
    if ((s0 == NULL) || (s1 == NULL))
        return NULL;

    while ((*s0++ = *s1++) && --len) //watch short circuit
        here
        ;
    return str;
}
```

## String Literals (Read-Only) in Expressions

- When strings in quotations (e.g., "string") are **part of** an **expression** (i.e., *not part of an array initialization*) they are called **string literals**

```
printf("literal\n");  
printf("literal %s\n", "another literal");
```

- What is a **string literal**:
  - Is a **null-terminated string** in a **const char array**
  - Located in the **read-only data segment of memory**
  - Is **not assigned a variable name** by the compiler, so it is only accessible by the location in memory where it is stored
- String literals** are a type of **anonymous variable**
  - Memory containing **data without a name bound** to them (only the address is known)
- The **string literal in the printf()'s**, are replaced with the **starting address of the corresponding array** (first or [0] element) when the code is compiled

# String Literals, Mutable and Immutable arrays - 1

- **mess1** is a **mutable** array (type is `char []`) with enough space to hold the string + `'\0'`

```
char mess1[] = "Hello World";  
*(mess1 + 5) = '\0'; // shortens string to "Hello"
```

`mess1[]` Hello World\0

- **mess2** is a **pointer** to an **immutable** array with space to hold the string + `'\0'`

```
char *mess2 = "Hello World"; // "Hello World" read only string literal  
// mess2 is a pointer NOT an array!
```

`mess2` → Hello World\0 ← read only string literal

- **mess3** is a **pointer** to a mutable array

```
char *mess3 = (char []) {"Hello World"}; // mutable string  
*(mess3 + 1) = '\0'; // ok
```

using the cast `(char [])`  
makes it mutable

`mess3` → Hello World\0 ← mutable string

## 2D Arrays

- Generic (uniform) 2D array format:

```
type name[rows][cols] = {{values}, ..., {values}};
```

- allocates a single, contiguous block of memory
- The array is organized in **row-major** format

```
// a 2-row, 3-column array of char
```

```
char matrix[2][3];
```

```
// a 2-row, 5-column (row length) array of ints
```

```
// Must specify row length, compiler counts rows
```

```
int grid[][5] = {  
    {0, 1, 2, 3, 4},  
    {5, 6, 7, 8, 9}  
};
```

[1][0]	[1][1]	[1][2]	[1][3]	[1][4]
[0][0]	[0][1]	[0][2]	[0][3]	[0][4]

```
grid[1][2] using pointers is *( *(grid + 1) + 2)
```

1 word (int = 4 bytes)

	?	high memory
grid[1][4]	9	0x0024
grid[1][3]	8	0x0020
grid[1][2]	7	0x001c
grid[1][1]	6	0x0018
grid[1][0]	5	0x0014
grid[0][4]	4	0x0010
grid[0][3]	3	0x000c
grid[0][2]	2	0x0008
grid[0][1]	1	0x0004
grid[0][0]	0	0x0000
		low memory

## 2D Array of Char (where elements may contain strings)

- 2D array of chars (where rows may include strings)
- Each row has the same fixed number of memory allocated
- All the rows are the same length regardless of the actual string length)
- The column size must be large enough for the longest string

high memory char aos2d[3][22] = {"my", "two dimensional", "char array"};

aos2d[2]	c	h	a	r		a	r	r	a	y	'\0'											
aos2d[1]	t	w	o		d	i	m	e	n	s	i	o	n	a	l		a	r	r	a	y	'\0'
aos2d[0]	m	y	'\0'																			

low memory

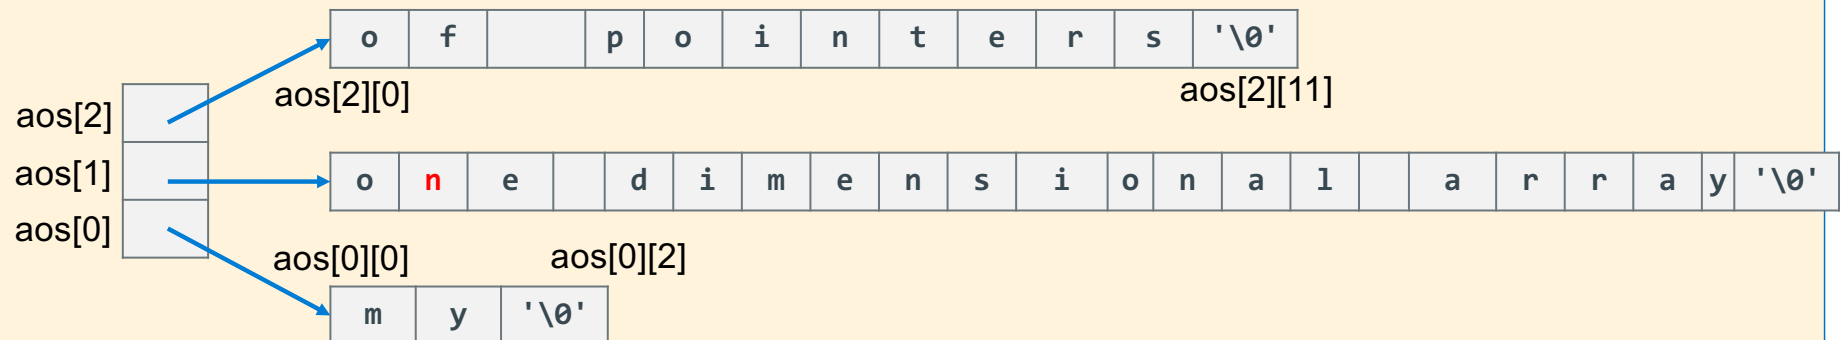

```
#define ROWS 3
char aos[ROWS][22] = { "my", "two dimensional", "char array"};
char (*ptc)[22] = aos; // ptr points at a row of 22 chars

for (int i = 0; i < ROWS; i++)
    printf("%s\n", *(ptc + i));
```

high memory

## Pointer Array to Strings (This is NOT a 2D array)

- 2D char arrays are an inefficient way to store strings (wastes memory) unless all the strings are similar lengths, so 2D char arrays are *rarely used* with string elements
- **An array of pointers** is common for strings as "rows" can vary in length
- `char *aos[3];`

- `aos` is an **array of pointers**; each pointer points at a **character array (also a string here)**
- **Not a 2D array**, but any char can be accessed as if it was in a 2D array of chars
  - When I was learning, this was the most confusing syntax aspects of C

## String Literals, Mutable and Immutable arrays - 2

- `mess4` is an array of pointers to immutable arrays

```
char *mess4[] = {"Hello","World"}; // immutable string  
*(*mess4 + 1) = '\0'; // bus error
```

Bus error: writing  
read only memory  
Seg fault: writing  
unallocated memory

- `mess5` is an array of pointers to mutable arrays

```
char *mess5[] = { (char []){"Hello"}, (char []){"World"}};  
*(*mess5 + 1) = '\0'; // OK!
```

## Pointer Array to Mutable Strings

- Make an **array of pointers** to **mutable strings** requires using a **cast to an array (char [ ])**
- Add a NULL sentinel at the end to indicate the end of the array

```
char *aos[] = {  
    (char []) {"abcde"},  
    (char []) {"fgh"},  
    (char *) {NULL}  
};  
char **ptc = aos;
```

```
printf("%c\n", (*(aos + 1) + 1));  
  
while (*ptc != NULL) {  
    printf("%s\n", *ptc);    // prints string  
  
    for (int j = 0; *(*ptc + j); j++)  
        putchar(*(*ptc + j)); // char in string  
  
    putchar('\n');  
    ptc++;  
}

# Pointer Array to Strings

How to access: `aos[1][1]` is `*(*(aos + 1) + 1)` which contains 'n'  
its address is `(*(aos + 1) + 1)`

aos+2 is not shown due to space limits on the slide

```
char *ptr;  
ptr = *aos;  
  
if (*ptr == ',')  
    or  
if (**aos) == ','
```

Notice that the first elements address is the array name

## main() Command line arguments: argc, argv

- Arguments are passed to main() as a pointer to an array of pointers (`**argv` or `*argv[]`)  
Conceptually: `% *argv[0] *argv[1] *argv[2] ...`
- `argc` is the number of VALID elements (they point at something)
- `*argv` (`argv[0]`) is **usually** is the **name** of the executable file (`% ./vim file.c`)
- `*(argv + argc)` always contains a NULL (0) sentinel
- `*argv[]` (or `**argv`) elements point at **mutable strings!**

```
printf("%s\n", *(argv+0));  
printf("%s\n", *(argv+1));  
printf("%s\n", *(argv+2));
```

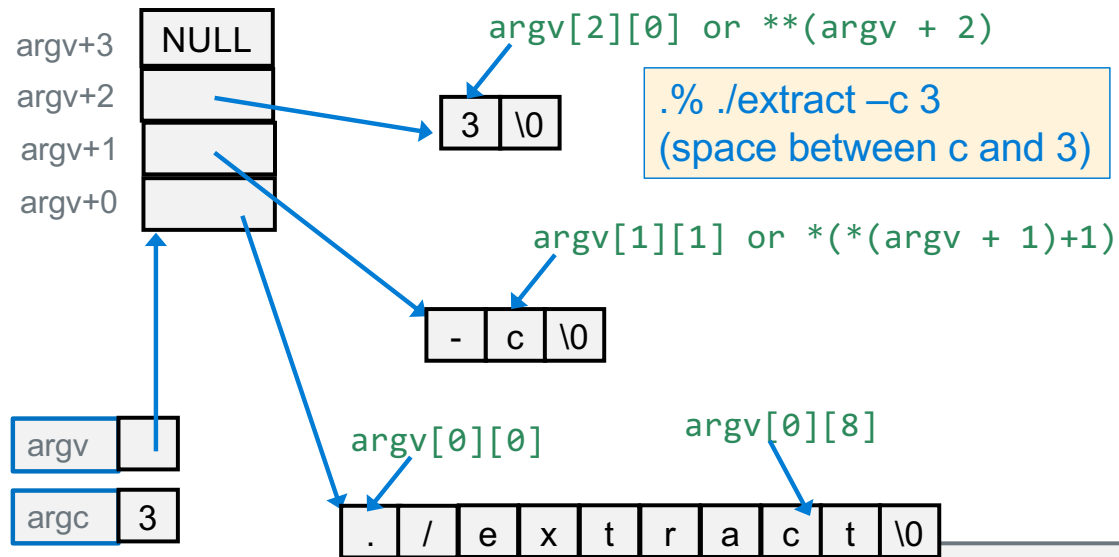

## main() Command line arguments: argc, argv

`argv[0][0]` equiv to `** (argv+0)`  
`** (argv+0)` equiv `**argv`  
`argv[0][8]` equiv `* ( * argv + 8 )`

```
char *pt = *argv;  
*pt equiv to **argv  
*(pt+8) equiv to * ( * argv + 8 )
```

## Printing argv char at a time

```
int main(int argc, char *argv[])
{
    (void)argc; // shut up the compiler
    for (int i = 0; argv[i] != NULL; i++) {
        for (int j = 0; argv[i][j] != '\0'; j++)
            putchar(argv[i][j]);
        putchar('\n');
    }
    return EXIT_SUCCESS;
}
```

```
int main(int argc, char **argv)
{
    char *pt;
    (void)argc; // shut up the compiler
    while ((pt = *argv++) != NULL) {
        while (*pt != '\0')
            putchar(*pt++);
        putchar('\n');
    }
    return EXIT_SUCCESS;
}
```

## main() Command line arguments: argc, argv

./extract -c 3  
(space between c and 3)

./extract -c3  
(No space between c and 3)

## Pointers to Functions (Function Pointers)

- Similar in concept to an array name, a **function name ends up being the address of the first instruction in a function**

- A function pointer variable contains the address of a function

- Generic format: `returnType (*name) (type1, ..., typeN)`

- Looks like a function prototype with extra \* in front of name
- Why are parentheses around (\*name) needed?

`returnType *name (type1, ..., typeN) //wrong`

- Above says name is a function returning a pointer to returnType

- Using the function:

`(*name) (arg1, ..., argN)`

`name (arg1, ..., argN)`

**Calls the pointed-to function with the given arguments and returns the return value**

## Pointers to Function Example

```
int main(void)
{
    int array[] = {4, 8, 15, 16, 23, 42};
    int cnt = sizeof(array)/sizeof(array[0]);

    print_array(array, cnt);

    array_update(add1, array, cnt);
    print_array(array, cnt);

    array_update(sqr, array, cnt);
    print_array(array, cnt);

    return EXIT_SUCCESS;
}
```

```
// array_update(f,a,len) (*f)() to each array element
void array_update(int (*f)(int), int *a, int len)
{
    for (int *p = a; p < a + len; ++p)
        *p = f(*p);
}
```

```
void print_array(int *a, int cnt)
{
    int *endp = a + cnt;
    for (int *p = a; p < endp; ++p)
        printf("%d ", *p);
    printf("\n");
}
```

```
int add1(int i)
{
    return i + 1;
}

int sqr(int i)
{
    return i * i;
}
```

```
./a.out
4 8 15 16 23 42
5 9 16 17 24 43
25 81 256 289 576 1849
```

## string buffer overflow: common security flaw

- A **buffer overflow** occurs when data is written **outside the boundaries** of the **memory allocated to target variable** (or target buffer)
- **strcpy()** is a very *common source of buffer overrun security flaws*:
  - always ensure that the **destination array is large enough** (and don't forget the null terminator)
- **strcpy()** can cause **problems** when the **destination** and **source regions overlap**

# strcpy() buffer overflow: over-write of an adjacent variable

```
int main(void)          /* file test.c */
{
    char s1[] = "before";
    char r2[4] = "xyz";
    char s2[] = "after";

    printf("s2: %s\nr2: %s\nr2:%s\n", s2, r2, s1);

    strcpy(r2,"hello"); // length > buffer size

    printf("\ns2:%s\nr2: %s\nr2:%s\n",s2,r2,s1);
    return EXIT_SUCCESS;
}
```

these are mutable  
arrays, not literals

compile on pi-cluster with  
gcc test.c

```
./a.out
s2: after
r2: xyz
s1: before

s2: after
r2: hello
s1: o
```

# The Heap Memory Segment

- Heap: “pool” of memory that is available to a program
  - Managed by C runtime library and linked to your code; **not managed by the OS**
- Heap memory is **dynamically** *"borrowed"* or *"allocated"* by calling a library function
- When heap memory is no longer needed, it is *"returned"* or *deallocated* for **reuse**
- Heap memory has a lifetime from allocation until it is deallocated
  - Lifetime is independent of the scope it is allocated in (it is like a static variable)
- If too much memory has already been allocated, the library will attempt to borrow additional memory from the OS and will fail, returning a NULL

# Heap Dynamic Memory Allocation Library Functions

<code>#include &lt;stdlib.h&gt;</code>	args	Clears memory
<code>void *malloc(...)</code>	<code>size_t size</code>	no
<code>void *calloc(...)</code>	<code>size_t nmem, size_t memsize</code>	yes
<code>void *realloc(...)</code>	<code>void *ptr, size_size</code>	no
<code>void free(...)</code>	<code>void *ptr</code>	no

- **void \*** means these library functions return a pointer to **generic (untyped) memory**
  - Be careful with void \* pointers and pointer math as void \* points at untyped memory (not allowed in C, but allowed in gcc). The assignment to a typed pointer *"converts"* it from a void \*
- **size\_t** is an **unsigned integer data type**, the result of a **sizeof()** operator

```
int *ptr = malloc(sizeof(*ptr) * 100); // allocate an array of 100 ints
```

- **please read: % man 3 malloc**

## Use of Malloc

```
void *malloc(size_t size)
```

- Returns a pointer to a **contiguous** block of **size** bytes of **uninitialized memory** from the heap
  - The block is **aligned to an 8-byte (arm32) or 16-byte (64-bit arm/intel) boundary**
  - **returns NULL** if allocation failed (also sets **errno**) **always CHECK for NULL RETURN!**
- Blocks returned on different calls to **malloc()** are not necessarily adjacent
- **void \*** is implicitly cast into any pointer type on assignment to a pointer variable

```
#include <stdlib.h>                // need this for malloc() etc
char *getbuf(int cnt)
{
    char *bufptr;
    /* ALWAYS CHECK THE RETURN VALUE FROM MALLOC!!!! */
    if ((bufptr = malloc(cnt * sizeof(*bufptr))) == NULL) {
        fprintf(stderr, "Unable to malloc memory");
        return NULL;
    }
    return bufptr;    // the calling function must free memory
}
```

## Use of Malloc

```
void *malloc(size_t size)
```

- Returns a pointer to a **contiguous** block of **size** bytes of **uninitialized memory** from the heap
  - The block is **aligned to an 8-byte (arm32) or 16-byte (64-bit arm/intel) boundary**
  - **returns NULL** if allocation failed (also sets **errno**) **always CHECK for NULL RETURN!**
- Blocks returned on different calls to **malloc()** are not necessarily adjacent
- **void \*** is implicitly cast into any pointer type on assignment to a pointer variable

```
#include <stdlib.h>                // need this for malloc() etc
char *getbuf(int cnt)
{
    char *bufptr;
    /* ALWAYS CHECK THE RETURN VALUE FROM MALLOC!!!! */
    if ((bufptr = malloc(cnt * sizeof(*bufptr))) == NULL) {
        fprintf(stderr, "Unable to malloc memory");
        return NULL;
    }
    return bufptr;    // the calling function must free memory
}
```

## Using and Freeing Heap Memory

- void **free**(void \*p)
  - Deallocates the **whole block pointed to by p** to the pool of available memory
  - Freed memory is used in future allocation (**expect the contents to change after freed**)
  - **Pointer p must be the same address as originally returned by one of the heap allocation routines malloc(), calloc(), realloc()**
  - Pointer argument to free() is not changed by the call to free()
- **Defensive programming: set the pointer to NULL after passing it to free()**

```
#define COLCNT 1024
char *ptr, *endptr, *bufptr;

bufptr = getbuf(COLCNT);      // do not lose bufptr!, NULL check not shown
ptr = bufptr;
endptr = ptr + COLCNT;
while (ptr < endptr)
    *ptr++ = 'a';             // fill each array element with 'a'
free(bufptr);                // returns memory to the heap
bufptr = NULL;               // set bufptr to NULL
```

# Heap Memory "Leaks"

- A **memory leak** is when you **allocate memory** on the heap, **but never free it**

```
void  
leaky_memory (void)  
{  
    char *bytes = malloc(BLKSZ * sizeof(*bytes));  
    ...  
    /* code that never deallocates the memory */  
    return;  
}
```

- **Best practice:** free up memory **you allocated** when you no longer need it
  - If you keep allocating memory, you may run out of memory in the heap!
- **Memory leaks** may cause **long running programs to fault** when they **exhaust OS memory limits**
- **Valgrind** is a tool for finding memory leaks (not pre-installed in all linux distributions though!)

## Valgrind – Finding Buffer Overflows and Memory leaks

```
1 #define SZ 50
2 #include <stdlib.h>
3 int main(void)
4 {
5     char *buf;
6     if ((buf = malloc(SZ * sizeof(*buf))) == NULL)
7         return EXIT_FAILURE;
8     *(buf + SZ) = 'A';
9     return EXIT_SUCCESS;
10 }
```

```
% valgrind -q --leak-check=full --leak-resolution=med -s ./valgexample

```

Writing outside of allocated  
buffer space

Memory not freed

## More Dangling Pointers: Reusing "freed" memory

- When a pointer points to a memory location that is no longer “valid”
- Really hard to debug as the use of the return pointers may not generate a seg fault

```
char *dangling_freed_heap(void)
{
    char *buff = malloc(BLKSZ * sizeof(*buff));
    ...
    free(buff);
    return buff;
}
```

- `dangling_freed_heap()` type code often causes the allocators (`malloc()` and friends) to **seg fault**
  - Because it corrupts data structures the heap code uses to manage the memory pool

## strdup(): Allocate Space and Copy a String

```
char *strdup(char *s);
```

- **strdup** is a function that returns a **null-terminated**, heap-allocated string copy of the provided text
- Alternative: **malloc** and copy the string

```
char *str = strdup("Hello, world!");  
*str = 'h';
```

```
free(str);  
str = NULL;
```

## Calloc()

```
void *calloc(size_t elementCnt, size_t elementSize)
```

calloc() variant of malloc() but zeros out every byte of memory before returning a pointer to it (so this has a runtime cost!)

- First parameter is the number of elements you would like to allocate space for
- Second parameter is the size of each element

```
// allocate 10-element array of pointers to char, zero filled  
char **arr;  
arr = calloc(10, sizeof(*arr));  
if (arr == NULL)  
    // handle the error
```

- Originally designed to allocate arrays but works for any memory allocation
  - calloc() multiplies the two parameters together for the total size
- calloc() is more expensive at runtime (uses both cpu and memory bandwidth) than malloc() because it must zero out memory it allocates at runtime
- Use calloc() only when you need the buffer to be zero filled prior to FIRST use

## Extra Slides

-

# Memory Size

- Since memory addresses are implemented in hardware using binary
  - The **Size (number of byte sized cells)** of Memory is specified in **powers of 2**
- Memory size/capacity in **bytes** is specified by the “**Number of bits**” in an address
  - 32 bits of address =  $2^{32} = 4,294,967,296$
  - Address Range is 0 to  $2^{32} - 1$  (unsigned)
- Shorthand notation for address size (Memory Capacity)
  - KB =  $2^{10}$  (K=1024) kilobyte
  - MB =  $2^{20}$  megabyte
  - GB =  $2^{30}$  gigabyte
  - TB =  $2^{40}$  terabyte
  - PB =  $2^{50}$  petabyte

## Fixed size types in C (later addition to C)

- Sometimes programs need to be written for a particular range of integers or for a particular size of storage, regardless of what machine the program runs on
- In the file `<stdint.h>` the following fixed size types are defined for use in these situations:

Signed Data types	Unsigned Data types	Exact Size
<code>int8_t</code>	<code>uint8_t</code>	8 bits (1 byte)
<code>int16_t</code>	<code>uint16_t</code>	16 bits (2 bytes)
<code>int32_t</code>	<code>uint32_t</code>	32 bits (4 bytes)
<code>int64_t</code>	<code>uint64_t</code>	64 bits (8 bytes)

## Defining Strings: Initialization Equivalents

- Following definitions create **equivalent** 4-character arrays
  - These are all strings as they all include a null ('\0') terminator

```
char a[4] = {'c', 'a', 't', '\0'};
char b[4] = {'c', 'a', 't', 0};
char c[4] = {'c', 'a', 't'};           // missing initial value defaults to 0
char d[4] = { 99, 97, 116, 0};         // 99 = 'c', 97 = 'a', 116 = 't'
char e[4] = "cat";
char f[4] = "cat\0";                   // literal has 5 chars; array f string
                                        // length is 3
```

## Pointer Practice

```
int *ptr;
```

Declares a variable, `ptr`, which is a pointer to (it contains the address of) an `int` in memory

```
int x = 5;
```

```
int y = 2;
```

Declares two variables, `x` and `y`, that contain `ints`, and *initializes* them to 5 and 2, respectively

```
ptr = &x;
```

Sets `ptr` to contain the address of `x` ("`ptr` points to `x`")

```
y = 1 + *ptr;
```

"Dereference `ptr`"

Sets `y` to "1 plus the value stored at the address held by `ptr`. Because `ptr` points to `x`, this is equivalent to `y = 1 + x`;

```
x = *(&y);
```

Sets `x = y`; The `*` and `&` cancel each other. get the address of `y` and then get the contents pointed by that address

`ptr` 

`x`  write

`y`  write

`ptr`   `x`  `y`  write

`ptr`   `x`  read `y`  write

`ptr`   `x`  write `y`  read

## strtol() and strtoul() examples of passing a pointer to a pointer

```
long int strtol(const char *str, char **endptr, int base);
```

```
unsigned long int strtoul(const char *str, char **endptr, int base);
```

reruns the string converted to a long or unsigned long

**str** pointer to the string to convert

**endptr** pass the address of a variable that is a char pointer (output variable)

**base**: number base used by the string

- **Example**: string is to contain just positive numbers  $\geq 0$  (in ascii) with no extra stuff
- If the string is not valid, then
  - **\*endptr** **!=** **'\0'** then string contains more than just numbers (bad input)
  - **\*endptr** stores the address of the first invalid character found in the buffer pointed (**str**)
- How to use **endptr** when it does not contain NULL:
  - If there are other conversion errors (you can read the man page) then **errno** **!=** 0
  - When conversion is ok, **errno** is unaltered (always clear it before calling these routines)

## strtol() and strtoul() examples of passing a pointer to a pointer

```
#include <stdlib.h>
#include <errno.h>
char *endptr;
char buf[] = "33"; // test buffer string
int number;

errno = 0; // set errno to 0 (zero) before each call
number = (int)strtol(buf, &endptr, 10)
// check if the string was a proper number
// *entpr should be at the end of the string == '\0'

if ((*endptr != '\0') || (errno != 0)) {
    // handle the error
}
printf("%d\n", number);
```

## Copying Strings: Use the Sentinel; libc: strcpy()

- To copy an array, you must copy each character from source to destination array
- Watch overwrites: strcpy assumes the target array size is equal or larger than source array

<i>index</i>	0	1	2	3	4	5
<i>char</i>	'H'	'e'	'l'	'l'	'o'	'\0'

```
char str1[80];  
strcpy(str1, "hello");
```

```
char *strcpy(char *s0, char *s1)  
{  
    char *str = s0;  
  
    if ((s0 == NULL) || (s1 == NULL))  
        return NULL;  
    while (*s0++ = *s1++)  
        ;  
    return str; // address of dest string  
}
```
